

What does the fetch() method do?

The fetch() method is used to send a request to the server and load information that was returned to the server on a web page. It accepts 2 parameters which are URL and options. Option is an object that consists of additional properties that can be sent to the server and is optional. Fetch() is compatible with all recent browsers except internet explorer so it allows for max compatibility.

Transversing means to find elements based on their relation to other elements. Three useful jQuery methods for transversing up the DOM tree are: parent() parents() and parentsUntil().
